Abstract:
The capability of involving the selection sharing encrypted data with different users via public cloud storage may greatly ease security concerns over not intended data leaks in the cloud. A key challenge to designing such encryption schemes to be sustainable in the efficient management of encryption keys. The desired flexibility of sharing any group of selected documents with any group of users need for something different encryption keys to be used for different documents. However, this also implies the urgent need of securely distributing to users a large number of keys for both encryption and search, and those users will have to protected from danger store the received keys, and submit an equally large number of keyword trapdoors to the cloud in order to perform search over the shared data implied need for secure communication, storage, and complexity clearly to give someone the approach impractical. In this work a data owner only needs to distribute a single key to a user for sharing a very large number of documents, and the user only needs to submit a single trapdoor to the cloud for querying the shared documents. User Revocation is used for Key Updation. Forward Secrecy and Backward Secrecy is used.

Keywords — Cloud Computing, Encryption, Decryption, Cipher text, Data Encryption, Information Storage & Retrieval.

I. INTRODUCTION

Cloud storage has emerged as a promising solving a problem for providing ubiquitous, convenient, and on-demand accesses to large amounts of data shared over the Internet. nowadays, millions of users are sharing personal data, such as photos and videos, with their friends through a dedicated website or other application which enables users to communicate with each and every other by posting information, messages, images based on cloud storage on a daily basis.

Business users are also being attracted by cloud storage due to its many benets, including lower cost, greater agility, and better resource utilization. However, while enjoying the quality of being useful, easy, of sharing data via cloud storage, users are also increasingly worried about inadvertent data leaks in the cloud. Such data leaks, caused by a malicious a misbehaving cloud operator, can usually lead to behave badly break or fail to observe of personal privacy or business secrets (e.g., the recent high prole incident of a famous person photos being leaked in iCloud).

To address users relate to protect potential data leaks in cloud storage, a prevalent way of dealing with a situation is for the data owner to encrypt all the data before upload to cloud.

II. LITERATURE SURVEY

Cloud computing is develop computing paradigm in which resources of the computing infrastructure are provided as services over the Internet. As to assure as it is, this paradigm also brings forth many new challenges for data security and access control when users outsource annoyed data for sharing on cloud servers, which are not within the same trusted
influence, as data owners. To keep sensitive user data confidential against untrusted servers, existing solutions usually apply cryptographic methods by only to appear data decryption keys to authorized users. The problem of simultaneously accomplish fine-grained access, scalability, and data confidentiality of access control actually still remains not resolved.

Success of data forensics in cloud computing is based on secure place that records ownership and process history of data objects. But it is the still challenging issue in this paper. In this paper, they proposed a new secure provenance scheme based on the bilinear pairing techniques. As the essential bread and butter of data forensics and postinvestigation in cloud computing, the proposed scheme is characterized by providing the information confidentiality on sensitive documents stored in cloud. Secure authentication on user access, and place tracking on disputed documents is provided in this paper. With the provable security techniques, this paper formally demonstrate the proposed scheme is secure in the standard model.

C. Mona: Secure Multi-Owner Data Sharing for Dynamic Groups in the Cloud.

In this paper character of low maintenance, cloud computing provides an economical and efficient solution for sharing group resource among cloud users. Due to the frequent change of membership sharing data in multi-owner manner while preserving data and identify privacy from untrusted cloud is still a challenging issue.

D. Key-Aggregate Crypto System for Scalable Data Sharing in Cloud Storage.

Data sharing is large functionality in cloud storage. In this article, we show how to securely, efficiently, and adaptable share data with others in cloud storage. The novelty is that one can aggregate any set of secret keys and make them as compact as a single key, but to enclose the power of all the keys being aggregated. In other words, the secret key something that holds or secures can release a constant-size aggregate key for flexible choices of ciphertext set in cloud storage, but the other encrypted files not inside the set unchanged confidential. This compact aggregate key can be suitable sent to others or be stored in a smart card with very limited secure storage.

III. METHODOLOGY

Through the concrete KASE scheme we address the challenges by proposing the new concept of key aggregate searchable encryption (KASE). By applying proposed KASE scheme to any cloud storage any user may selectively share group of selected files with a group of selected users.

User revocation is used in the proposed system. In user revocation forward secrecy and backward secrecy is used. User revocation is used for the key updation in the cloud storage. Forward secrecy means if any user is added into the group the aggregate is forward to the new member of the group.

Backward secrecy is if any group member is leaves from the group the aggregate key is updated in the server. And the new aggregate key is informed to the existing group members. Because of the user revocation the data is more secure in the cloud.

In the concrete KASE scheme user only needs to submit a single trapdoor to the cloud for querying the shared documents. And data owner only needs to distribute a single key to user for sharing a large number of documents. Maintaining aggregate key is easy in server and for the group members. KASE alice only need to distribute a single aggregate key instead of multiple keys. It is an efficient public-key encryption scheme which supports flexible delegation. In this work we uses the AES algorithm for the encryption and decryption of data.
IV. CONCLUSIONS

Considering the practical problem of privacy maintain data sharing system based on public cloud storage which requires a data owner to distribute a large number of keys to users to enable them to access his/her documents. Analysis and assessment results confirm that our work can provide an effective solution to building practical data sharing system based on public cloud storage. When sharing a lot of documents with the user the owner only to distribute a single key. User only need to submit a single trapdoor when all documents are shared by the same owner. In spite of that, if a user wants to query over documents shared by multiple owners, he must generate multiple trapdoors to the cloud. The future work is to reduce the number of trapdoors under multi-owners setting. The inter clouds have attracted a lot of attention nowadays. But the KASE cannot be applied in this kind of case directly. In case of inter clouds and federated clouds to provide a solution for these is a future work.
